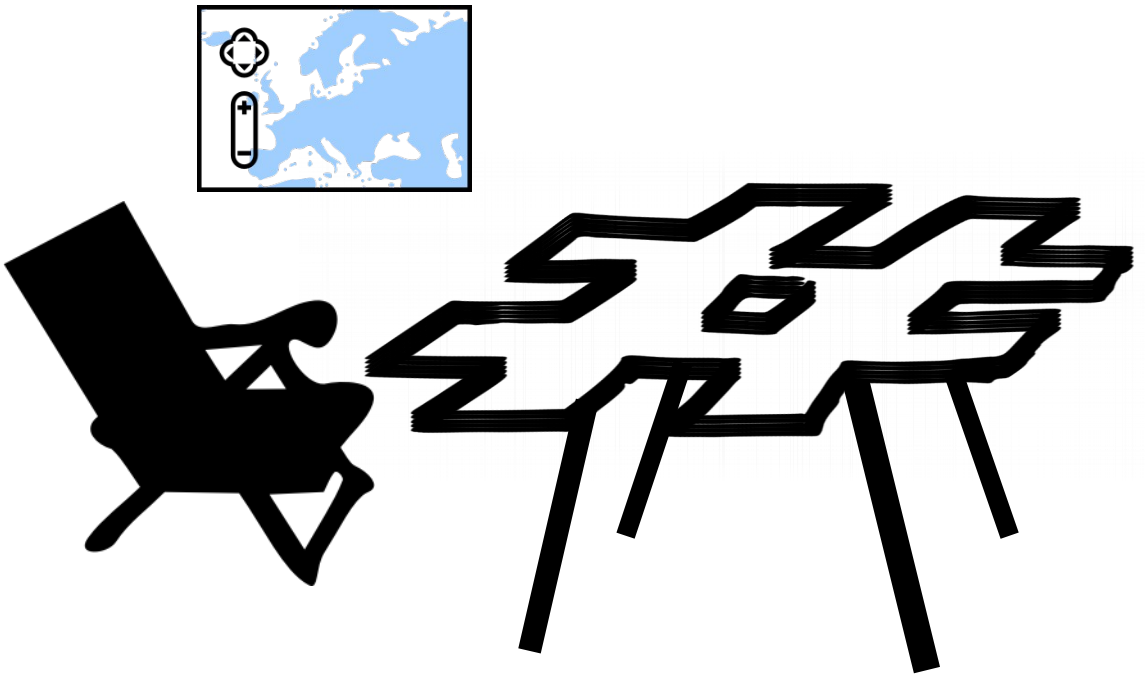
Mike Lam, Professor



Maps and Hash Tables

ADTs

- List
- Set
- Stack
- Queue
  - Deque
  - Priority Queue

New ADT: Map

- Map: key → value
- Unique keys, non-unique values
- Other names:
  - Dictionary
  - Associative array
- Many applications
  - Database: student ID# → student info
  - DNS: domain name → IP address
  - OS: process ID → process record
  - Namespace: variable → value

Map ADT

- **`set`**`(M,k,v)` `modify value for key`
- **`get`**`(M,k)` retrieve value for key
- **`contains`**`(M,k)` return true if key has a mapping
- `remove(M,k)` remove key from map
- `size(M)` return # of keys
- `clear(M)` remove all mappings
- `key_set(M)` return a set of all keys
- `value_set(M)` return a set of all values

Map Implementations

- Unsorted array
  - Insert: Lookup: Modify:
- Sorted array
  - Insert: Lookup: Modify:
- Skip list / AVL tree
  - Insert: Lookup: Modify:

Map Implementations

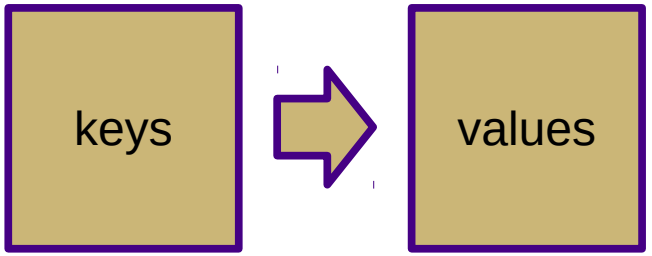
- Unsorted array
  - Insert: ***O(n)*** Lookup: ***O(n)*** Modify: ***O(n)***
- Sorted array
  - Insert: ***O(n)*** Lookup: ***O(log n)*** Modify: ***O(log n)***
- Skip list / AVL tree
  - Insert: ***O(log n)*** Lookup: ***O(log n)*** Modify: ***O(log n)***

Map Implementations

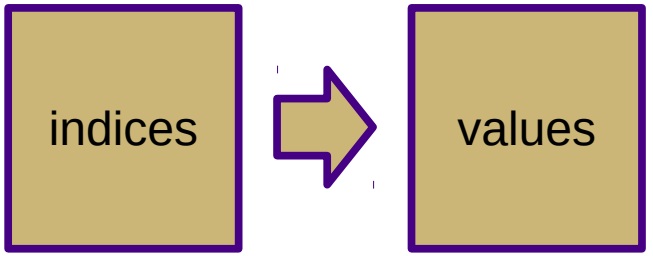
- Unsorted array
  - Insert: ***O(n)*** Lookup: ***O(n)*** Modify: ***O(n)***
- Sorted array
  - Insert: ***O(n)*** Lookup: ***O(log n)*** Modify: ***O(log n)***
- Skip list / AVL tree
  - Insert: ***O(log n)*** Lookup: ***O(log n)*** Modify: ***O(log n)***
- Hash table
  - Insert: ***O(1)*** Lookup: ***O(1)*** Modify: ***O(1)***

Hash Tables

- Custom data structure for fast key/value lookups
  - Used to implement the Map ADT
  - Goal: *O(1)* access (insert/modify/delete)
    - So we can't use comparisons (remember sorting?)
- Observation: arrays provide *O(1)* access
  - How to map from keys to array indices?
  - How large does the array need to be?



Map ADT

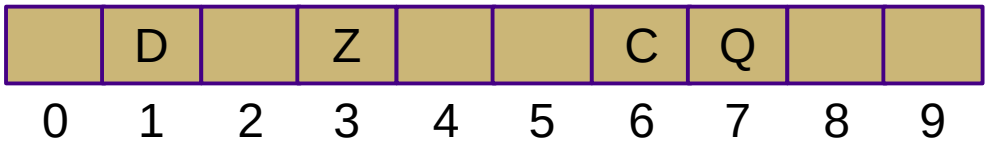


Array

Hash Tables

- Simple case: keys are integers in [0, *N*)
  - Create an array of length *N*
  - Use keys directly as indices into the array
- This does not scale!
  - *N* could be very large
  - Keys might not be integers

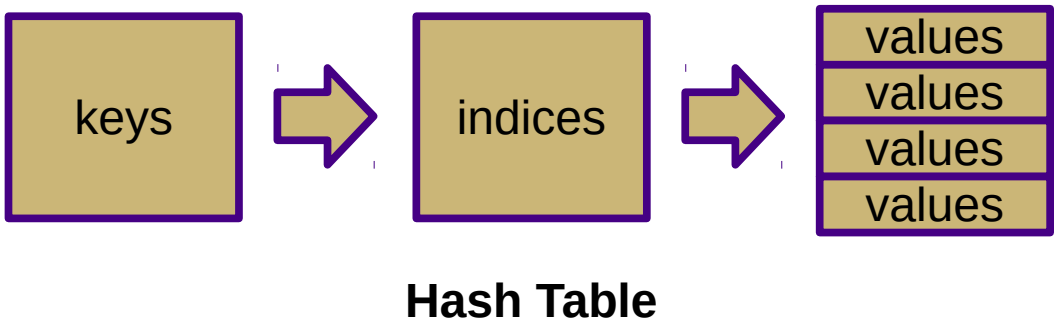
```
char t[10];
t[3] = 'Z';
t[6] = 'C';
t[7] = 'Q';
t[1] = 'D';
```



Items: (1,D), (3,Z), (6,C), (7,Q)

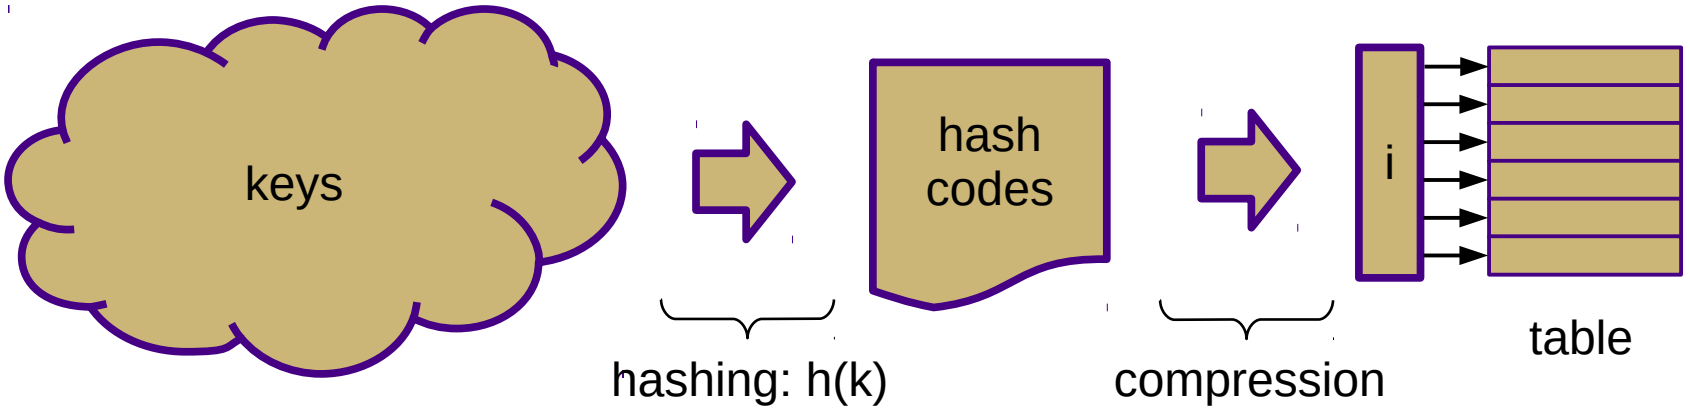
Hash Tables

- Main concept: hash function
  - Converts keys → table indices
  - Table holds "buckets" of elements



Hash Functions

- Hash code (key → 32/64-bit integer)
  - Translation from key domain to hash code domain
  - Key can be any immutable object
  - Hash codes are usually native integers
- Compression function (hash code → table index)
  - Compression from hash code domain to index domain
  - Result is used to access table storage



Hash Codes

- Most codes are based on interpreting raw bits as integers
  - Issue: key size may be greater than native integer width
- Need to combine multiple integers
  - Truncation
  - Summation
  - Exclusive-or (XOR)

  } bad for variable-length objects

  - Polynomial combination
  - Cyclic shifting
  - Cryptographic hashes (e.g., MD5, SHA-1)

Compression Functions

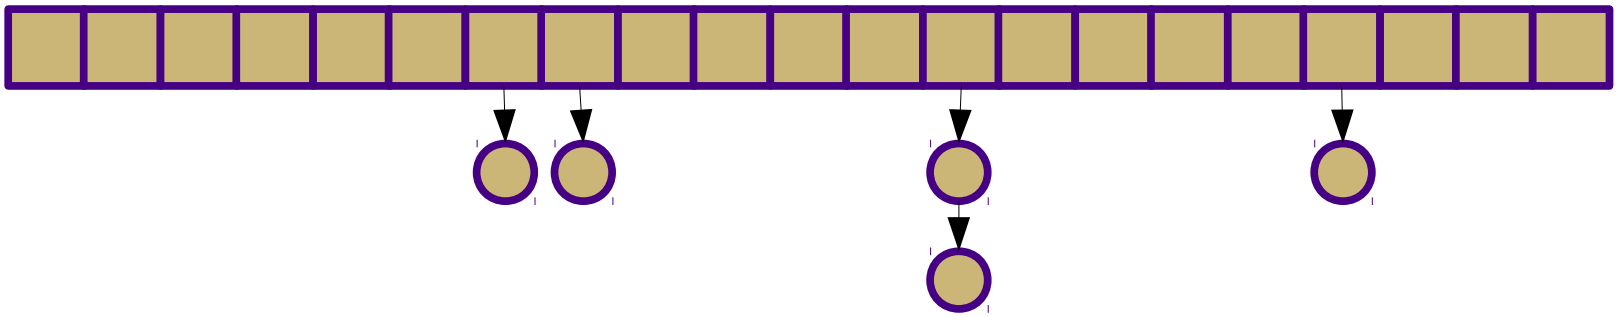
- Simplest: Modulus division
  - $h' = h(k) \% N$
  - N is the number of buckets in the hash table
  - N should be a prime number
- Better: Multiply-Add-and-Divide
  - $h' = ((a \cdot h(k)) + b) \% p) \% N$
  - p is a prime number larger than N
  - a and b are random integers from [0, p-1]
    - $a > 0$
  - Essentially a pseudo-random number generator that uses hash codes as seeds

Hash Functions

- Major problem: **collisions**
  - Multiple keys that map to the same index
  - Two-fold approach:
    - Minimize collisions by choosing a good hash code
    - Handle collisions with chaining or probing

Collision Handling

- Separate chaining
  - Each bucket is a linked list of elements
  - Load factor: $\lambda = n/N$
    - Expected size of each bucket
    - If the hash function is good, map operations run in $O(\lambda)$
    - This should be a small constant
      - Preferably less than 1
    - As long as λ is $O(1)$, map operations run in $O(1)$ expected time

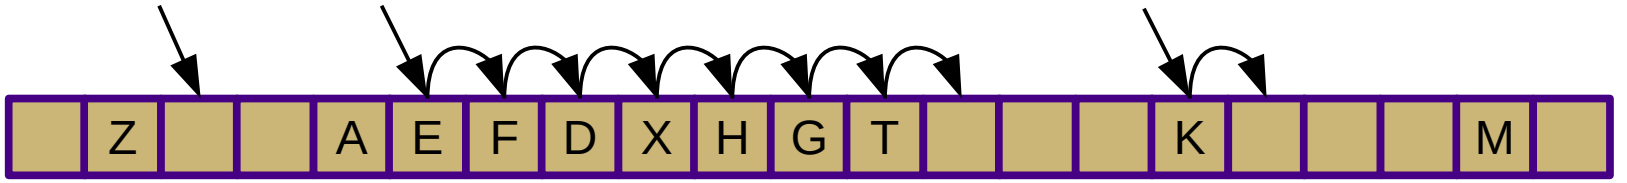


Collision Handling

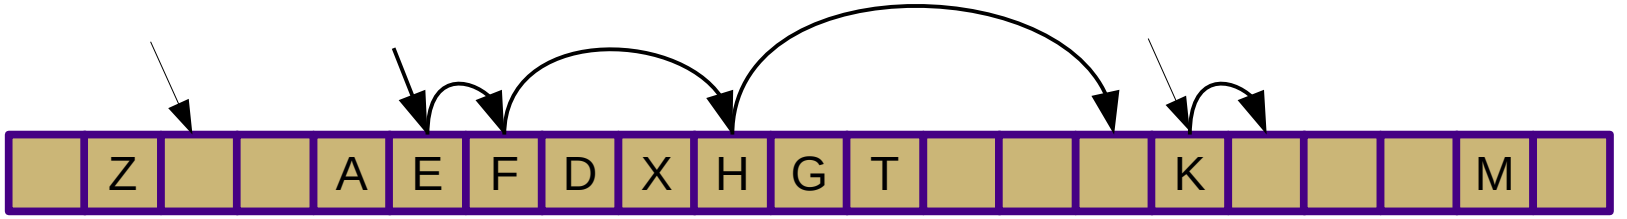
- Open addressing / probing
  - Only one (key, value) pair per "bucket"
  - Problem: *h′(k)* not guaranteed to be open
  - Probing scheme to find an open bucket
  - Load factor: $\lambda = n/N$
    - Percentage of buckets that are occupied
  - Allowing removal of keys from a map can break this scheme!
- Approaches
  - Linear probing: $(h'(k) + i) \% N$
  - Quadratic probing: $(h'(k) + i^2) \% N$
  - Double hashing: $(h'(k) + i \cdot h''(k)) \% N$
  - Pseudo-random probing: $(h'(k) + prand(i)) \% N$

Open Addressing

- Linear probing

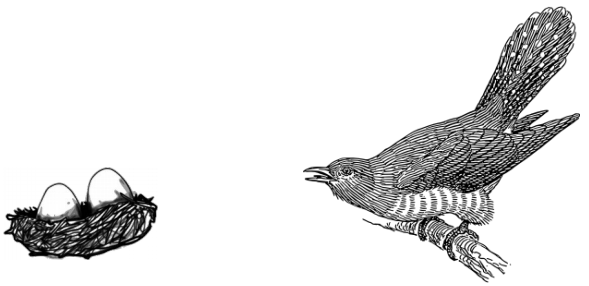


- Quadratic probing



Collision Handling

- Coalesced hashing (hybrid chained/open)
  - Maintain chains as pointers between buckets
  - Avoids some of the overhead of probing
- Cuckoo hashing (multiple hash functions)
  - Use multiple hash functions (primary and alternate)
  - If new key's bucket is full, remove existing key and re-insert it using alternate hash
  - Repeat until empty bucket is found or an infinite loop is detected



Load Factors

- Separate chaining
  - Want to keep λ less than 1 (preferably < 0.9)
- Open addressing
  - Want to keep λ less than 1/2 or 2/3
- Rehashing
  - When constraints above are violated, resize the hash table and re-apply the compression function to re-insert all keys
  - Cost can be amortized by doubling the table size
    - Just as with dynamic arrays

Hashing Analysis

- The expected # of keys in a bucket is *ceil*(*n/N*)
  - This is *O(1)* if n is *O(N)*
  - Assumes a good hash function
  - Assumes enforcement of appropriate load factor
- Thus, expected costs for major map operations (insertion, modification, lookup, removal) are all *O(1)*
  - Worse case: *O(n)*
- Full probabilistic analysis is beyond the scope of this class

Retrospective

- Set/Map equivalence
  - A Set is a Map with no values
  - A Map is a Set of keys with associated values
  - In general, any implementation of one can be used for the other
- Progression of Set/Map implementations:
  - Array / linked list
    - Mostly *O(n)* operations
  - Skip list / AVL tree
    - Mostly *O(log n)* operations
  - Hash table
    - Mostly *O(1)* operations
