

CS 261

Fall 2017

Mike Lam, Professor

x86-64 Control Flow

Topics

- Condition codes
- Jumps
- Conditional moves
- Jump tables

Motivation

- Can we translate the following C function to assembly, using only data movement and arithmetic operations?

```
int min (int x, int y)
{
    if (x < y) {
        return x;
    } else {
        return y;
    }
}
```

Motivation

- Can we translate the following C function to assembly, using only data movement and arithmetic operations?
 - **No!**

```
int min (int x, int y)
{
    if (x < y) {
        return x;
    } else {
        return y;
    }
}
```

Motivation

- Can we translate the following C function to assembly, using only data movement and arithmetic operations?
 - Fundamental requirement: ability to **control** the **flow** of program execution (i.e., decision-making)
 - Necessary for translating **structured** code

```
int min (int x, int y)
{
    if (x < y) {
        return x;
    } else {
        return y;
    }
}
```

Control flow

- The **program counter** (PC) tracks the address of the next instruction to be executed
 - To change the PC in assembly, use a **jump** instruction
 - Often the jump will be relative to the current PC value
 - In assembly, the target of a jump is usually a **label**, which is converted to a code address by the assembler
 - Labels are written using colon notation
 - However, **unconditional** jumps aren't sufficient for decision-making
 - In fact, the compiler can just re-arrange code to avoid them

```
    movl $2, %eax
    jmp L1
    movl $3, %eax      # never executed!
L1:
    movl $4, %eax
```

Control flow

- **Conditional jumps** only jump under certain conditions
 - Compilers translate **block-structured** code to **linear** code using conditional jumps
 - We can do this in C using the **goto** statement
 - General template: `"if (<cond>) goto <label>;"`
 - Syntax for labels is the same in C and assembly (colon notation)
- CS:APP: C “**goto code**” is code that uses only `if/goto` and **goto**
 - No blocks (and therefore no “else” blocks or explicit loops)
 - Not a good idea in general!
 - Famous letter by Dijkstra: “Go To Statement Considered Harmful”
 - However, it is useful for pedagogical purposes (closer to assembly)

Example

C code:

```
if (x < y) {  
    printf("A");  
} else {  
    printf("B");  
}  
printf("C");
```

**note inverted
condition!**

C goto code:

```
    if (x >= y) goto L1;  
    printf("A");  
    goto L2;  
L1:  
    printf("B");  
L2:  
    printf("C");
```

C code:

```
while (x < 5) {  
    x = x - 1;  
}
```

C goto code:

```
    goto L2;  
L1:  
    x = x - 1;  
L2:  
    if (x < 5) goto L1;
```

Conditional jumps

- In machine/assembly code, conditional jumps are encoded using a pair of instructions
 - The first sets the **condition codes** of the CPU
 - On x86-64, the FLAGS register
 - Any arithmetic or logical instruction will do this as a side effect, but there are a couple of special instructions that are commonly used specifically to set them
 - The second makes a jump depending on the value of the condition codes
 - On x86-64, many different variants

Condition codes

- In x86-64: special `%flags` register stores individual bits for the following condition codes:
 - **CF** (carry): last operation resulted in a carry out (indicates overflow for unsigned arithmetic)
 - **ZF** (zero): last operation yielded zero
 - **SF** (sign): last operation yielded a negative value
 - **OF** (overflow): last operation caused a two's complement overflow (negative or positive)

Condition codes

- Special **cmp** and **test** instructions
 - **cmp** compares two values (computes $\text{arg}_2 - \text{arg}_1$)
 - **NOTE REVERSED ORDERING** – also, the result is not saved
 - Type-agnostic: all flags are set, but not all are relevant!
 - **test** checks bits (computes $\text{arg}_2 \& \text{arg}_1$)
 - Often, the arguments are the same (or one is a bit mask)

```
cmpl %eax, %ecx           # means "compare %ecx with %eax"
```

```
testl $0xFF, %edx        # means "check low-order 8 bits of %edx"
```

Jump instructions

Instruction	Synonym	Jump condition	Description
jmp <i>Label</i>		1	Direct jump
jmp <i>*Operand</i>		1	Indirect jump
j _e <i>Label</i>	j _z	ZF	Equal / zero
j _{ne} <i>Label</i>	j _{nz}	~ZF	Not equal / not zero
j _s <i>Label</i>		SF	Negative
j _{ns} <i>Label</i>		~SF	Nonnegative
j _g <i>Label</i>	j _{nle}	~(SF ^ OF) & ~ZF	Greater (signed >)
j _{ge} <i>Label</i>	j _{nl}	~(SF ^ OF)	Greater or equal (signed >=)
j _l <i>Label</i>	j _{nge}	SF ^ OF	Less (signed <)
j _{le} <i>Label</i>	j _{ng}	(SF ^ OF) ZF	Less or equal (signed <=)
j _a <i>Label</i>	j _{nbe}	~CF & ~ZF	Above (unsigned >)
j _{ae} <i>Label</i>	j _{nb}	~CF	Above or equal (unsigned >=)
j _b <i>Label</i>	j _{nae}	CF	Below (unsigned <)
j _{be} <i>Label</i>	j _{na}	CF ZF	Below or equal (unsigned <=)

Type
difference

Figure 3.15 The jump instructions. These instructions jump to a labeled destination when the jump condition holds. Some instructions have “synonyms,” alternate names for the same machine instruction.

Example

C code:

```
int min (int x, int y)
{
    if (x < y) {
        return x;
    } else {
        return y;
    }
}
```

x86-64 assembly: (x in %edi, y in %esi)

```
min:
    cmpl %esi, %edi
    jge .L3
    movl %edi, %eax
    ret
.L3:
    movl %esi, %eax
    ret
```

Example

C code:

```
int min (int x, int y)
{
    if (x < y) {
        return x;
    } else {
        return y;
    }
}
```

x86-64 assembly: (x in %edi, y in %esi)

```
min:          y      x
             cmpl    %esi, %edi
             jge     .L3
             movl    %edi, %eax
             ret
.L3:
             movl    %esi, %eax
             ret
```

Example

C code:

```
int min (int x, int y)
{
    if (x < y) {
        return x;
    } else {
        return y;
    }
}
```

x86-64 assembly: (x in %edi, y in %esi)

```
min:
    cmpl %esi, %edi
    jge .L3
    movl %edi, %eax
    ret
.L3:
    movl %esi, %eax
    ret
```

Example

C code:

```
int min (int x, int y)
{
    if (x < y) {
        return x;
    } else {
        return y;
    }
}
```

x86-64 assembly: (x in %edi, y in %esi)

```
min:
    cmpl %esi, %edi
    jge .L3
    movl %edi, %eax
    ret
.L3:
    movl %esi, %eax
    ret
```

Conditionals (in goto code)

```
if (<test-expr>
    <true-branch>
else
    <false-branch>
```

```
if (!<test-expr>)
    goto false;
<true-branch>
goto done;
false:
    <false-branch>
done:
```

If/else

```
if (<top-expr>
    if (<test-expr>
        <true-branch>
    else
        <false-branch>
else
    <else-branch>
```

```
if (!<top-expr>)
    goto else;
if (!<test-expr>)
    goto false;
<true-branch>
goto done;
false:
    <false-branch>
done:
    goto end;
else:
    <else-branch>
end:
```

Nested
if/else

Conditionals (in goto code)

```
if (<test-expr>
    <true-branch>
else
    <false-branch>
```

```
if (!<test-expr>)
    goto false;
<true-branch>
goto done;
false:
    <false-branch>
done:
```

If/else

```
if (<top-expr>
    if (<test-expr>
        <true-branch>
    else
        <false-branch>
else
    <else-branch>
```

```
if (!<top-expr>)
    goto else;
if (!<test-expr>)
    goto false;
<true-branch>
goto done;
false:
    <false-branch>
done:
    goto end;
else:
    <else-branch>
end:
```

Nested
if/else

Conditional moves

- Similar to conditional jumps, but they move data if certain condition codes are set
 - Benefit: no **branch prediction** penalty
 - We'll see how this produces faster code in a few weeks
 - In C code: "`x = (<cond> ? <tvalue> : <fvalue>)`"

```
    cmpq %rax, %rbx
    jg  L01
    movq %rax, %rcx
    jmp L02
L01:
    movq %rbx, %rcx
L02:
```

```
    movq %rax, %rcx
    cmpq %rax, %rbx
    cmovg %rbx, %rcx
```

Conditional moves

- Similar to conditional jumps, but they move data if certain condition codes are set
 - Benefit: no **branch prediction** penalty
 - We'll see how this produces faster code in a few weeks
 - In C code: "x = (<cond> ? <tvalue> : <fvalue>)"

```
    cmpq %rax, %rbx
    jg  L01
    movq %rax, %rcx
    jmp L02
L01:
    movq %rbx, %rcx
L02:
```

```
    movq %rax, %rcx
    cmpq %rax, %rbx
    cmovg %rbx, %rcx
```

Loops

- Basic idea: jump back to an earlier label
- Three basic forms:
 - Do-while loops
 - Jump-to-middle loops
 - Guarded-do loops
- Note: we'll use goto code in C first
 - Just to avoid unnecessary complication
 - If you can translate a loop into goto code, it's then much easier to convert to assembly

Loops

do *<body-statement>*
while (*<test-expr>*);

loop:
 <body-statement>
 if (*<test-expr>*)
 goto loop;

Do-while
loop

while (*<test-expr>*)
 <body-statement>

goto test;
loop:
 <body-statement>
test:
 if (*<test-expr>*)
 goto loop

Jump-to-
middle
loop

if (!*<test-expr>*)
 goto done
loop:
 <body-statement>
 if (*<test-expr>*)
 goto loop
done:

Guarded-
do loop

Loops

do *<body-statement>*
while (*<test-expr>*);

loop:
 <body-statement>
 if (*<test-expr>*)
 goto loop;

Do-while
loop

while (*<test-expr>*)
 <body-statement>

goto test;
loop:
 <body-statement>
test:
 if (*<test-expr>*)
 goto loop

Jump-to-
middle
loop

if (!*<test-expr>*)
 goto done
loop:
 <body-statement>
 if (*<test-expr>*)
 goto loop
done:

Guarded-
do loop

Loops

```
for (<init-expr>; <test-expr>; <update-expr>)  
    <body-statement>
```

```
    goto test;  
loop:  
    <body-statement>  
test:  
    if (<test-expr>)  
        goto loop
```

Jump-to-middle loop

```
    if (!<test-expr>)  
        goto done  
loop:  
    <body-statement>  
    if (<test-expr>)  
        goto loop  
done:
```

Guarded-do loop

Loops

```
for (<init-expr>; <test-expr>; <update-expr>)  
  <body-statement>
```

```
<init-expr>  
goto test;  
loop:  
  <body-statement>  
  <update-expr>  
test:  
  if (<test-expr>)  
    goto loop
```

Jump-to-middle loop

```
<init-expr>  
if (!<test-expr>)  
  goto done;  
loop:  
  <body-statement>  
  <update-expr>  
  if (<test-expr>)  
    goto loop  
done:
```

Guarded-do loop

Switch statements

- One approach: convert to if/elseif code
 - Problem: performance varies based on ordering and actual runtime values!

```
switch (x) {  
  case 10: do_blah();  
           break;  
  case 11: do_foo();  
           break;  
  case 13: do_bar();  
           break;  
  case 15: do_baz();  
           break;  
  default: error();  
}
```

```
if (x == 10) {  
  do_blah();  
} else if (x == 11) {  
  do_foo();  
} else if (x == 13) {  
  do_bar();  
} else if (x == 15) {  
  do_baz();  
} else {  
  error();  
}
```

Switch statements

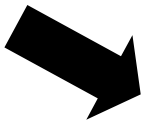

- Indexed **indirect jump** ("computed goto")
 - Jump to an address stored in a register
 - Implemented using a data structure called a jump table
 - Efficient when # of options is high and the value range is small

```
switch (x) {  
    case 10: do_blah();  
             break;  
    case 11: do_foo();  
             break;  
    case 13: do_bar();  
             break;  
    case 15: do_baz();  
             break;  
    default: error();  
}
```

Jump Table

<u>Index</u>	<u>Destination</u>
0	0x400e51
1	0x400e88
2	0x401900
3	0x400f12
4	0x401900
5	0x400f34

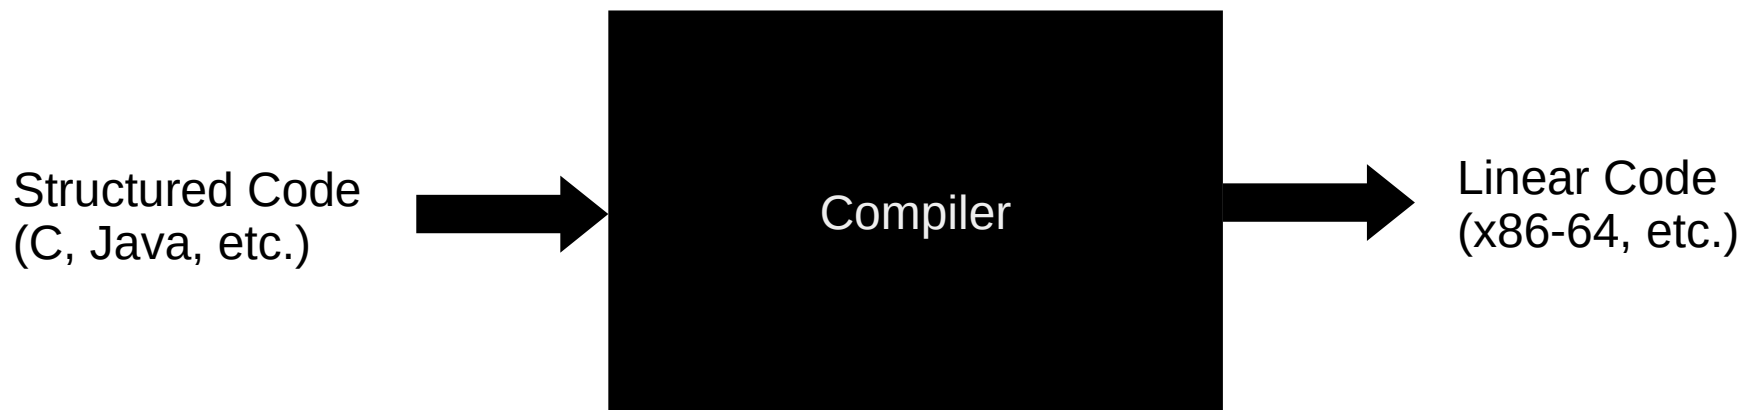

x is in %rdx, address of jump table is in %rbx

```
subq $0xA, %rdx  
movq (%rbx,%rdx,0x8), %rcx  
jmp  *%rcx
```

Related coursework

- Intriguing notion: can we **always** automatically translate from structured code to linear/goto code?
 - Yes, this is what a compiler does!
 - If you're interested in learning more about how this works, plan to take CS 432 as your systems elective

Exercise

- Convert the following C function into x86-64 assembly:

```
int sum = 0;
int x = 1;
while (x < 10) {
    sum = sum + x;
    x = x + 1;
}
```

Exercise

- Convert the following C function into x86-64 assembly:

```
int sum = 0;
int x = 1;
while (x < 10) {
    sum = sum + x;
    x = x + 1;
}
```

```

movl    $0, %eax        # sum = 0
movl    $1, %edx        # x = 1
jmp     L2              # goto L2

L1:
addl    %edx, %eax      # sum = sum + x
addl    $1, %edx        # x = x + 1

L2:
cmpl    $10, %edx       # if (x < 10)
jl      L1              # goto L1

```
