Fall 2018

Mike Lam, Professor

Sequential Circuits

Circuits

- Circuits are formed by linking gates (or other circuits) together
  - Inputs and outputs
    - Link output of one gate to input of another
    - Some circuits have multiple inputs and/or outputs
  - Combinational circuits: outputs are a boolean function of inputs
    - Not time-dependent
    - Used for computation
  - Sequential circuits: output is dependent on previous outputs
   - Time-dependent
    - Used for memory

Circuit memory

- Question: How do we make a circuit "remember" something?
  - Answer: Create a feedback loop!
  - Creates a "storage" circuit, often called a latch
  - Truth table must include previous state
  - Alternatively, draw a timing diagram
    - Shows how input/output signals change with respect to time
    - Given input signals in diagram, we can determine output signals
# SR AND-OR latch

S = "set"   R = "reset"
SR NOR latch

Works similarly to AND-OR, but requires one fewer gate (and it is a universal gate!)

Question: What happens if we turn both R and S on at the same time?

**Disallow S=1, R=1 because Q' ≠ !Q**

D latch

From "Code" book: S = "Save that bit!"

- As long as S is on, Q reflects the value of D.

- When S turns off, Q is "frozen" and retains its previous value.

- D can change while S is off with no change in Q

Signal changes

- The original D latch reflects D input on Q as long as "set" is on
- Edge-triggered latches change Q on rising edge of "set" signal
- Master-slave latches change Q on falling edge of "set" signal
Edge-triggered D latch
Master-slave D latch

Master-slave D latch

Original D latch:

Master-slave D latch:

Clocks

- Provide oscillating signal
- Often used as "set" signal for latches
- Keeps computation and memory in sync
- Clocked latches are called flip-flops
- The clock period is the inverse of the frequency (measured in *hertz*)
- The length of a clock period determines the minimum time an instruction takes to execute

Clk

Clock period = $1 / f$
Flip-flop types

- **SR**: "set-reset"
- **D**: "data" bit + clock
- **T**: "toggle"
- **JK**: like SR + T (toggle when S=1, R=1)
  - J is S, K is R
- Any of these can be used to build the others
- Also can be built from basic logic gates in multiple ways

Registers

- Registers: arrays of flip-flops with a single set/clock input
- Connected by buses (groups of wires) to other components
- Edge triggering allows computation to stabilize before results are saved
- Caveat: difference between hardware registers and program registers
 - Former are physical, latter are logical (and stored in a register file)
Register files

- Register files: multiple registers w/ selector inputs
 - Use multiplexors to differentiate

CS:APP version

Memory

- Memory: multiple flip-flops w/ address input
  - Random access memory (RAM) - can access any address at any time
  - Use decoder (translates 3-bit number to 8 "set" signals) to write data
 - Use selector (multiplexor) to read data

Single RAM array
Abstraction of multiple RAM arrays

Counters

- Uses rippled flip-flops w/ feedback to count
  - Similar to adders

ALUs and memory

- Combine adders and multiplexors to make arithmetic/logic units
- Combine flip-flops to make register files and main memory

Basic Arithmetic Logic Unit (ALU)

8-bit Register

CPUs

- Combine ALU with registers and memory to make CPUs
