Exceptional Control Flow and Processes
Exceptional control flow

- Most control flow is sequential
  - However, we have seen violations of this rule
    - (e.g., exceptions in Java or segfaults in C)
Exceptional control flow

- **Exceptions** violate sequential control flow
  - Unconditional transfer to another location in code
  - Often the result of an error condition
    - But not necessarily – we can also use exceptions for time-sharing!
  - Categorized as **asynchronous vs. synchronous**
    - Whether it happens as a result of an external source or not
  - Categorized by **recovery possibility**
    - Always returns, sometimes returns, or never returns
  - If recovery is possible, further categorized by **recovery location**
    - Same instruction vs. next instruction
Interrupts

- **Interrupt**: communication mechanism
  - Asynchronous, always returns to next instruction
  - “Interrupts” execution as the result of an outside event
    - An I/O operation has finished
    - The process has finished its time slice
Traps

- **Trap**: intentional control transfer to kernel
  - Synchronous, (almost) always returns to next instruction
  - Like a function call, except the target runs in kernel mode
  - Also referred to as **system calls**
  - x86-64 instruction “syscall” w/ ID in %rax
  - Parameters are passed in %rdi-%r9; return value stored in %rax
  - Well-known standards (e.g., POSIX)
Some of the functions we've been using in C are actually wrappers for a system call (or multiple system calls)

- `fopen`, `fread`, `malloc`
  - System calls: `open` (id=2), `read` (id=0), `mmap` (id=9)
- System call interfaces are defined by standards
  - SysV vs. POSIX (IEEE standard: http://pubs.opengroup.org/onlinepubs/9699919799/)
- In general, system call wrappers are called system-level functions
- It is important to check for errors after calling these functions
  - Textbook uses wrapper functions (e.g., "Open") for this

```c
int fd = open("file.txt", O_RDONLY);
if (fd < 0) {
    fprintf(stderr, "Error opening file: %s\n", strerror(errno));
    exit(EXIT_FAILURE);
}
```
Textbook notes

• Error handling is important!
  – Textbook provides error-handling wrappers; this is good practice
  – However, we’ll omit error handling to simplify examples

• `envp` parameter to `main()` is not standard
  – `getenv()` is the only environmental mechanism defined by the POSIX C99 standard
• **Fault**: error that is potentially correctable
  - Synchronous, sometimes returns to same instruction
  - We have already seen some of these!
- **Fault**: error that is potentially correctable
  - Synchronous, sometimes returns to same instruction
  - Page fault (#14): virtual memory cache miss
    - Recoverable – read the required page from slower memory
  - Segmentation fault (#13): invalid memory access
    - Not recoverable – undefined behavior
  - Divide-by-zero error (#0)
    - Not recoverable – undefined result

![Diagram](image)
**Aborts**

- **Abort**: unrecoverable error
  - Synchronous, never returns
  - Machine check (#18): fatal hardware error

![Diagram of abort process]

1. **Fatal hardware error occurs**
2. Control passes to handler
3. Abort handler runs
4. Handler returns to abort routine

Abort
Exception implementation

- Kernel exception table
  - Every exception is assigned a unique ID
  - Table translates exception ID to handler address
Processes

• Exceptions enable processes
  - **Process**: a running program
    • One program, (possibly) many processes
  - Abstraction provided by OS kernel
    • One kernel, many user processes
  - Shared portion of virtual address space
    • Kernel memory (above stack)
    • This region is not visible to user programs
  - Toggle control (kernel and processes)
    • **Interrupts** – cycle through processes ("round robin")
    • **Traps** – function call from processes into kernel ("syscalls")
    • **Faults** – software error (recover or abort)
    • **Aborts** – stop process without taking down the machine
**Processes**

- **Process**: instance of an executing program
  - Independent single logical flow and private virtual address space
- **Logical flow**: sequence of executed instructions
- **Concurrency**: overlapping logical flows
- **Multitasking**: processes take turns
- **Parallelism**: concurrent flows on separate CPUs/cores

![Diagram showing the relationship between time, logical flow, concurrent flows, multitasking concurrent flows, and parallel concurrent flows.](image-url)
Implementing processes

- Processes are abstractions
  - Implemented/provided by the operating system kernel
  - Kernel maintains data structure w/ process information
    - Including an ID for each process (pid)
  - Multitasking via exceptional control flow
    - Periodic interrupt to switch processes
    - Called round-robin switching
  - **Context switch**: swapping current process
    - Save context of old process
    - Restore context of new process
    - Pass control to the restored process
Linux process tools

- **ps** – list processes
  - "ps -fe" to see all processes on the system
  - "ps -fu <username>" to see your processes
- **top** – list processes, ordered by current CPU
  - Auto-updates
- **/proc** – virtual filesystem exposing kernel data structures
- **pmap** – display memory map of a process
- **strace** – prints a list of system calls from a process
  - Compile with "-static" to get cleaner traces
Process creation

• The `fork()` syscall creates a new process
  – Initializes new entry in the kernel data structures
  – **To user code, the function call returns twice**
    • Once for original process (parent) and once for new process (child)
    • Returns 0 in child process
    • Returns child pid in parent process
    • Both processes will continue executing concurrently
  – Parent and child have separate address spaces
    • Child's space is a duplicate of parent's at the time of the fork
    • They will diverge after the fork!
  – Child inherits parent's environment and open files
Process creation example

- Fork returns twice!

```c
int main ()
{
    printf("Before fork\n");
    pid_t pid = fork();
    printf("After fork: pid=%d\n", pid);
    return 0;
}
```
What does this code do?

```c
int main ()
{
    printf("Before fork\n");

    pid_t pid1 = fork();

    printf("After fork: pid1=%d\n", pid1);

    pid_t pid2 = fork();

    printf("After second fork: pid1=%d pid2=%d\n", pid1, pid2);

    return 0;
}
```
Process creation example

- Fork returns twice! (every time)
  - Beware of non-determinism and I/O interleaving

```c
int main ()
{
    printf("Before fork\n");

    pid_t pid1 = fork();

    printf("After fork: pid1=%d\n", pid1);

    pid_t pid2 = fork();

    printf("After second fork: pid1=%d pid2=%d\n", pid1, pid2);

    return 0;
}
```

Exercise: Modify this program to fork a total of three processes
Parents can wait for children to finish

```c
int main ()
{
    printf("Before fork\n");

    pid_t pid = fork();

    if (pid != 0) {     // parent
        wait(NULL);
        printf("Child has terminated.\n");
    } else {            // child
        printf("Child is running.\n");
    }

    printf("After fork: pid=%d\n", pid);

    return 0;
}
```
Process control syscalls

- **#include `<stdlib.h>`**
  - `getenv`: get environment variable value
  - `setenv`: change environment variable value
- **#include `<sys/types.h>`**
  - `pid_t`: new type for PID value
- **#include `<unistd.h>`**
  - `fork`: create a new process
  - `getpid`: return current process id (pid)
  - `getppid`: return parent's process id (pid)
  - `exit`: terminate current process
  - `execve`: load and run another program in the current process
  - `sleep`: suspend process for specified time period
- **#include `<sys/wait.h>`**
  - `waitpid`: wait for a child process to terminate
  - `wait`: wait for all child processes to terminate
Processes and shells

- **A shell** is an interactive application-level program that launches other programs (called **jobs** or **process groups**)
  - All spawned as a result of the same command
- **Foreground vs. background jobs**
  - A single foreground job (interactive I/O)
  - Zero or more background jobs
  - Use `&` to start something in the background
    - Ex: `./my_prog &`
  - Use **CTRL-Z** to send foreground job to background
  - Use **CTRL-C** to interrupt the foreground job
  - **fg**: promote background job to foreground
Fork/execve example

• Shells use `fork()` and `execve()` to run commands

```c
int main ()
{
    printf("Before fork\n");
    pid_t pid = fork();

    if (pid != 0) {    // parent
        wait(NULL);
        printf("Child has terminated.\n");
    } else {            // child
        printf("Child is running.\n");
        char *cmd    = "/bin/uname";
        char *args[] = { "uname", "-a", NULL };
        char *env[]  = { NULL };
        execve(cmd, args, env);
        printf("This won't print unless an error occurs.\n");
    }

    printf("After fork: pid=%d\n", pid);
    return 0;
}
```
