

# CS 149

Professor: Kevin Molloy

(adapted from slides originally developed by Alvin Chao)

# JAVA is Portable

Most “high-level” languages are considered portable because they can be compiled into machine code for any computer:

# Java Compilation

**Byte Code Files** are portable because there are JVM's that run on most machines

The **same** compiled byte code works on any JVM

# Anatomy of a Java Program: Comments

## Javadoc comments:

```
/**  
 * Application that converts inches to centimeters.  
 *  
 * @author Chris Mayfield  
 * @version 01/21/2014  
 */
```

Everything between `/**` and `*/` ignored by compiler  
Used to generate code documentation

Block comments are used for text that should *not* be part of the published documentation:

```
/*  
    Permission is hereby granted, free of charge, to any  
    person obtaining a copy of this software and associated  
    documentation files (the "Software"), to deal in the  
    Software without restriction.  
*/
```

In-line comments are used for short clarifying statements:

```
// Create a scanner for standard input.
```

# Anatomy of a Java Program: Classes

Java is an **object-oriented language** (OO)

Java classes tie together instructions and data

All Java code **must** exist within some class

```
public class ConvertInches {  
  
}
```

`public` and `class` are **keywords**: Words that have a special meaning for Java.

`public` – (more later)

`class` – Create a class with the following name. (Must match the file name)

Class names are always capitalized (by convention)

Braces { and } enclose **blocks** of code

# Anatomy of a Java Program: Methods

**Method** – named collection  
of Java statements:

```
public class ConvertInches {  
    public static void main(String[] args) {  
    }  
}
```

Later

# Anatomy of a Java Program: Methods

**Method** – named collection of Java statements:

```
public class ConvertInches {  
    public static void main(String[] args) {  
    }  
}
```

Later

return type  
(void means  
nothing is  
returned)

# Anatomy of a Java Program: Methods

**Method** – named collection of Java statements:

```
public class ConvertInches {  
    public static void main(String[] args) {  
    }  
}
```

Later

return type  
(void means  
nothing is  
returned)

method name  
"main" is the  
starting point for all  
Java programs

# Anatomy of a Java Program: Methods

**Method** – named collection of Java statements:

```
public class ConvertInches {  
  
    public static void main(String[] args) {  
  
    }  
}
```

Later

return type  
(`void` means nothing is returned)

method name  
"main" is the starting point for all Java programs

argument type  
`String[]` means that this method takes an array of Strings.

# Anatomy of a Java Program: Methods

**Method** – named collection of Java statements:

argument name  
args will be an array of Strings from the command line.  
args[0], args[1], etc.

```
public class ConvertInches {  
  
    public static void main(String[] args) {  
  
    }  
}
```

Later

return type  
(void means nothing is returned)

method name  
"main" is the starting point for all Java programs

argument type  
String[] means that this method takes an array of Strings.

# Anatomy of a Java Program: Declaring and Assigning Variables

**variable** – named box for storing data:

## type

Defines what the variable can hold

## name

Should always be informative. “x” is not OK.

```
int inch;  
double cent;  
final double CENT_PER_INCH;  
  
CENT_PER_INCH = 2.54;
```

# Anatomy of a Java Program: Declaring and Assigning Variables

**variable** – named box for storing data:

## type

Defines what the variable can hold

## name

Should always be informative. “x” is not OK.

```
int inch;  
double cent;  
final double CENT_PER_INCH;  
  
CENT_PER_INCH = 2.54;
```

## assignment

Puts the value on the right into the variable on the left.

ALWAYS RIGHT TO LEFT!

literal value

# Anatomy of a Java Program: Declaring and Assigning Variables

**variable** – named box for storing data:

## type

Defines what the variable can hold

## name

Should always be informative. “x” is not OK.

## final

makes this variable a constant

```
int inch;  
double cent;  
final double CENT_PER_INCH;
```

## assignment

Puts the value on the right into the variable on the left.  
ALWAYS RIGHT TO LEFT!

```
CENT_PER_INCH = 2.54;
```

literal value

# Printing Output to the Screen

Two functions for printing:

- `System.out.println()`
- `System.out.print()`

What is the difference between these two functions?

# Printing Output to the Screen

```
System.out.print("Hello, world!\n");
```

```
System.out.print("Hello, world!\n");
```

`System.out.println` includes the “newline” character.

Special characters are preceded by a backslash (`\`) character (which is not printed).

- How do you print a backslash?
- How do you print a double quotation mark?

# Printing Output to the Screen

Escape Sequence	Meaning
\\	Print a single backslash
\t	Print a tab character
\n	Print a newline character
\"	Print a double quotation mark
