# Alternate Definition of Big-O

## Big O

$f(n) \in O(g(n))$  if

$$\lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = c < \infty$$

where  $c$  is some constant (possibly 0)

# Alternate Definitions of Big-O

## Big O

$f(n) \in O(g(n))$  if

$$\lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = c < \infty$$

where  $c$  is some constant (possibly 0)

- $n^3 + 2n \in n^3$

# Alternate Definitions of Big-O

## Big O

$f(n) \in O(g(n))$  if

$$\lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = c < \infty$$

where  $c$  is some constant (possibly 0)

- $n^3 + 2n \in n^3$

$$\lim_{n \rightarrow \infty} \frac{n^3 + 2n}{n^3} = \lim_{n \rightarrow \infty} 1 + \frac{2}{n^2} = 1$$

# Alternate Definitions of $O$ , $\Omega$ , $\Theta$

## Big $\Omega$

$f(n) \in \Omega(g(n))$  if

$$\lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = c > 0$$

where  $c$  is some constant (possibly  $\infty$ )

# Alternate Definitions of $O$ , $\Omega$ , $\Theta$

## Big $\Theta$

$f(n) \in \Theta(g(n))$  if

$$\lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = c, 0 < c < \infty$$

where  $c$  is some constant.

# A Complication

- Let's analyze this algorithm:

```
1 public static boolean contains(int target,
2                               int[] numbers) {
3     for (int number : numbers) {
4         if (number == target) {
5             return true;
6         }
7     }
8     return false;
9 }
```

# Best, Worst, Average Case

```
1 public static boolean contains(int target,
2                               int [] numbers) {
3     for (int number : numbers) {
4         if (number == target) {
5             return true;
6         }
7     }
8     return false;
9 }
```

- Best Case: 1 comparison,  $O(1)$
- Worst Case:  $n$  comparisons,  $O(n)$
- Average Case:  $\frac{n+1}{2}$  comparisons,  $O(n)$

# Refined Algorithm Analysis Algorithm

- STEP 1: Decide on best, worst, or average case analysis
- STEP 2: Select a measure of input size and a basic operation
- STEP 3: Find a function  $T(n)$  that describes the number of times the basic operation occurs
- STEP 4: Describe  $T(n)$  using order notation:
  - Big-O for an upper bound  
“The algorithm is at least this fast!”
  - Big- $\Omega$  for a lower bound  
“The algorithm is at least this slow!”
  - Big- $\Theta$  for both upper and lower bound

# L'Hôpital's Rule

## L'Hôpital's Rule

If  $\lim_{n \rightarrow \infty} f(n) = \lim_{n \rightarrow \infty} g(n) = \infty$  and  $f'(n)$  and  $g'(n)$  exist, then

$$\lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = \lim_{n \rightarrow \infty} \frac{f'(n)}{g'(n)}$$

# L'Hôpital Example

- $n \log_2 n \stackrel{?}{\in} O(n^2)$

# L'Hôpital Example

- $n \log_2 n \stackrel{?}{\in} O(n^2)$
- $\lim_{n \rightarrow \infty} \frac{n \log_2 n}{n^2} = \lim_{n \rightarrow \infty} \frac{\log_2 n}{n}$

# L'Hôpital Example

- $n \log_2 n \stackrel{?}{\in} O(n^2)$
- $\lim_{n \rightarrow \infty} \frac{n \log_2 n}{n^2} = \lim_{n \rightarrow \infty} \frac{\log_2 n}{n}$
- $= \lim_{n \rightarrow \infty} \frac{\ln n}{n \ln 2}$  (Recall that  $\log_b(n) = \frac{\log_k n}{\log_k b}$ )

# L'Hôpital Example

- $n \log_2 n \stackrel{?}{\in} O(n^2)$
- $\lim_{n \rightarrow \infty} \frac{n \log_2 n}{n^2} = \lim_{n \rightarrow \infty} \frac{\log_2 n}{n}$
- $= \lim_{n \rightarrow \infty} \frac{\ln n}{n \ln 2}$  (Recall that  $\log_b(n) = \frac{\log_k n}{\log_k b}$ )
- Apply L'Hôpital's rule:
- $= \lim_{n \rightarrow \infty} \frac{\frac{1}{n}}{\ln 2}$  (Recall that  $\frac{d}{dx} \ln x = 1/x$ )

# L'Hôpital Example

- $n \log_2 n \stackrel{?}{\in} O(n^2)$
- $\lim_{n \rightarrow \infty} \frac{n \log_2 n}{n^2} = \lim_{n \rightarrow \infty} \frac{\log_2 n}{n}$
- $= \lim_{n \rightarrow \infty} \frac{\ln n}{n \ln 2}$  (Recall that  $\log_b(n) = \frac{\log_k n}{\log_k b}$ )
- Apply L'Hôpital's rule:
- $= \lim_{n \rightarrow \infty} \frac{\frac{1}{n}}{\ln 2}$  (Recall that  $\frac{d}{dx} \ln x = 1/x$ )
- $= \lim_{n \rightarrow \infty} \frac{1}{n \ln 2} = 0$

# What If We Want to Show That $f(n)$ is NOT $O(g(n))$

- Easiest approach is usually to show:

$$\lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = \infty$$

# OpenDSA Question

Suppose that a particular algorithm has time complexity  $T(n) = 3 \times 2^n$  and that executing an implementation of it on a particular machine takes  $t$  seconds for  $n$  inputs. Now suppose that we are presented with a machine that is 64 times as fast. How many inputs could we process on the new machine in  $t$  seconds?

# OpenDSA Question

- Let's call the input size we could handle before  $n_{old}$ . The number of steps we completed in  $t$  seconds was:  $3 \times 2^{n_{old}}$ .
- Since our new computer is 64 times faster, the number of steps we can perform in  $t$  seconds is now  $64 \times 3 \times 2^{n_{old}}$
- Our complexity function tells us that  $steps = 3 \times 2^n$ , we can solve for size ( $n$ ):
- $s = 3 \times 2^n$
- $s/3 = 2^n$
- $\log_2(s/3) = n$
- $n = \log_2(s/3)$

# OpenDSA Question

Now we plug in our step budget for  $s$ :

- $n = \log_2\left(\frac{64 \times 3 \times 2^{n_{old}}}{3}\right)$

- $n = \log_2(64 \times 2^{n_{old}})$

- $n = \log_2(2^6 \times 2^{n_{old}})$

- $n = \log_2(2^{n_{old}+6})$

- $n = n_{old} + 6$
